

PHASE 1: THE CONTRACT

Core Features (IN SCOPE)

Shorten: Long URL → Short Alias

Redirect: Short Alias → Long URL

Custom Alias (Optional)

Expiration Date (Optional)

~~Out of Scope~~

~~User Authentication~~

~~Complex Analytics Dashboards~~

~~Link Editing~~

NON-FUNCTIONAL REQUIREMENTS

Scale: 100M Daily Active Users | 1 Billion URLs

100:1

Read : Write Ratio

Latency: < 200ms (Redirects)

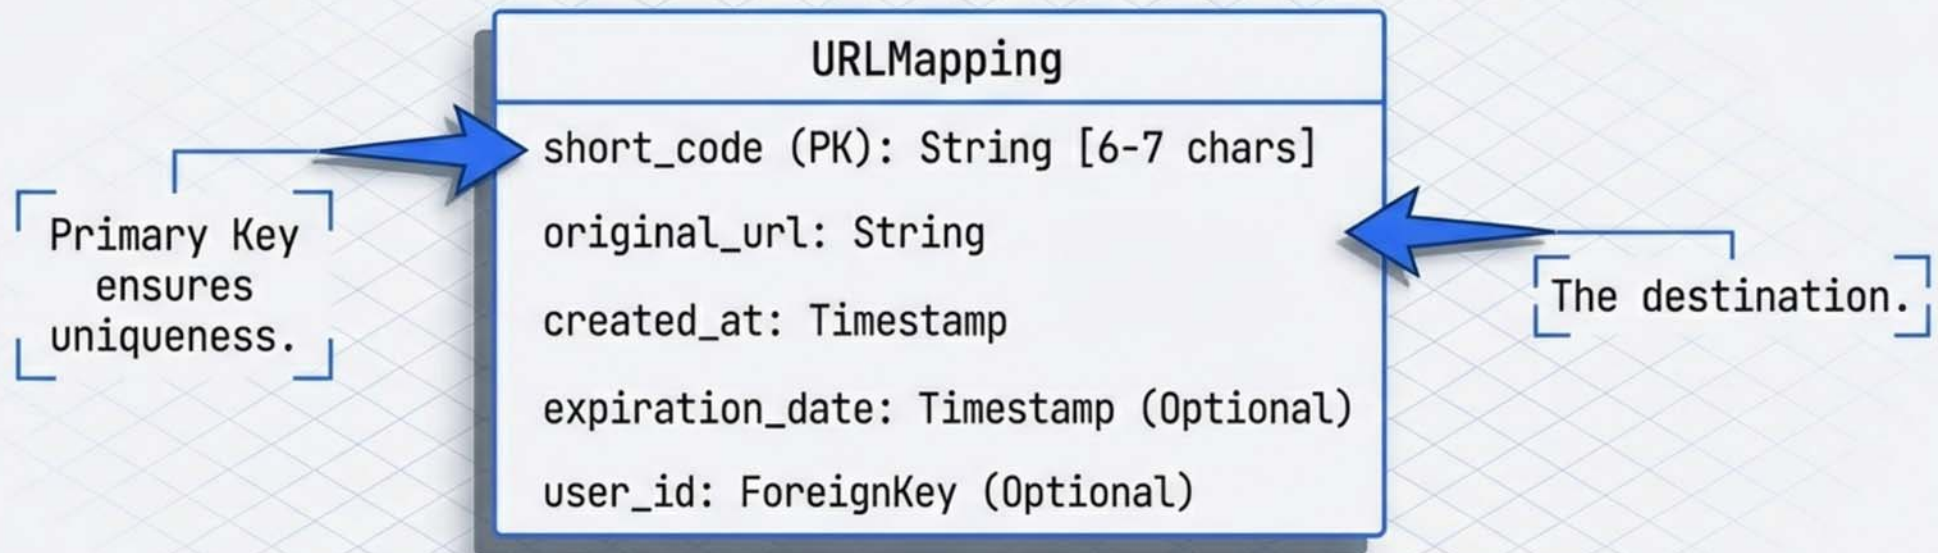

Availability: AP System
(High Availability > Consistency)

**Read-Heavy
System**

Phase 2: The Core Entities

Phase 3: The API Contract

Create Short URL

POST /api/urls/shorten

Request Body:

```
{  
  "long_url": "https://www.example.com/....",  
  "alias": "custom-name" (optional)  
}
```

Response: 200 OK

```
{ "short_url": "bit.ly/custom-name" }
```

Redirect User

GET /api/urls/{shortCode}

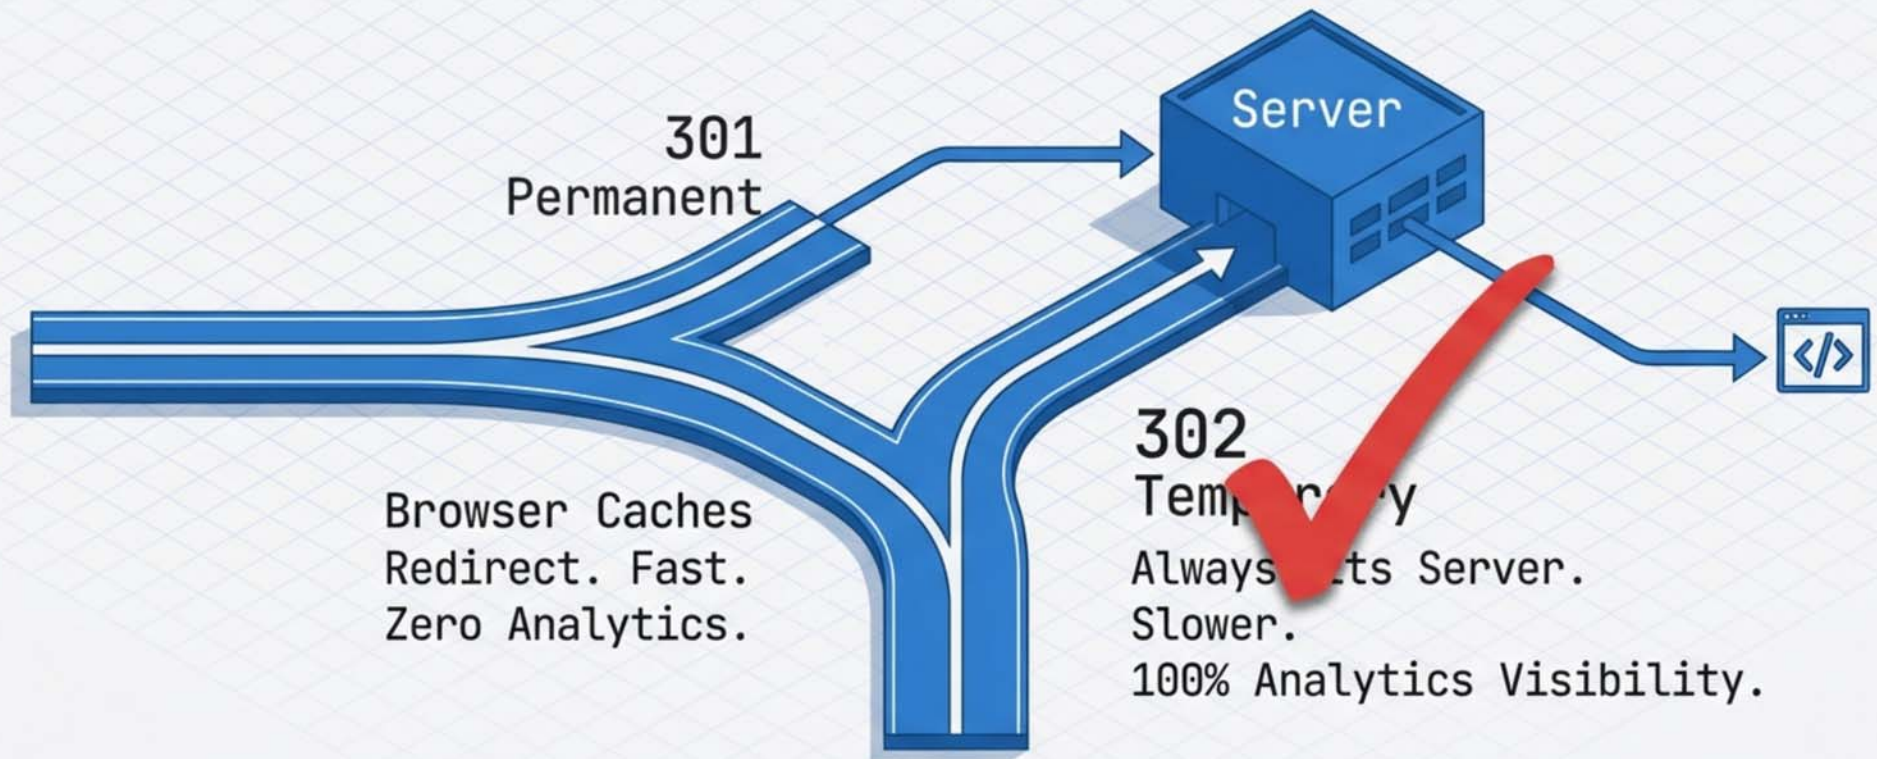

Response: 302 Found

Location: <https://www.example.com/...>

Phase 4: High-Level Design (The Happy Path)

The Redirect Decision: 301 vs. 302

Business Requirement: Analytics drive revenue.

Generating the Short Code

MD5 Hashing

Too long.
Collisions when
truncated.

Random Gen

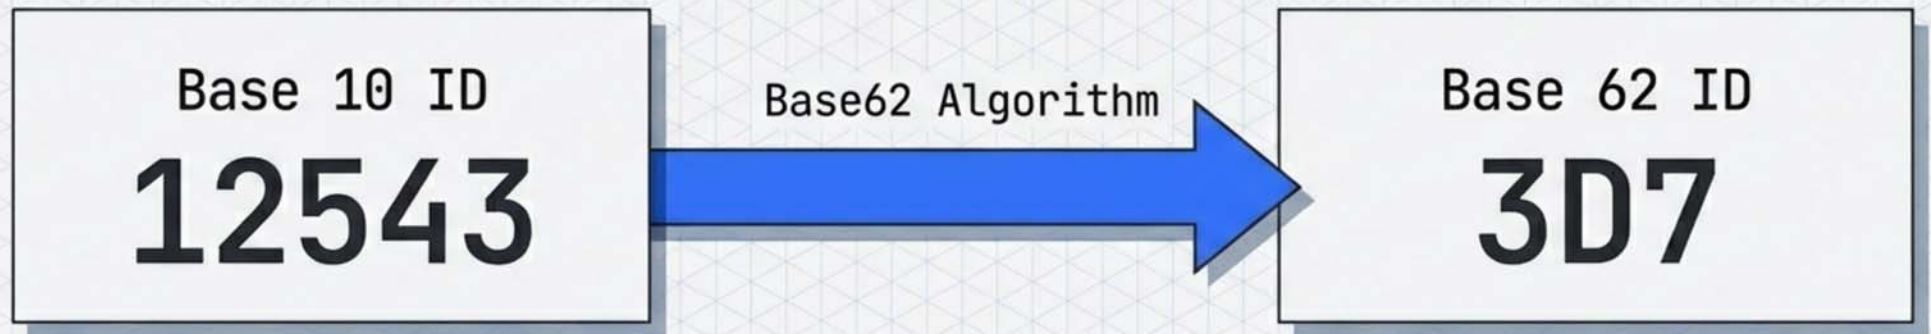

Collision risk
increases
over time. **Requires**
"Check-Then-Write".

The Counter

Zero Collisions.
Sequential.
Fast.

Base62 Encoding

$$[a-z] (26) + [A-Z] (26) + [0-9] (10) = 62 \text{ Characters}$$

$62^6 \approx 56.8$ Billion Combinations

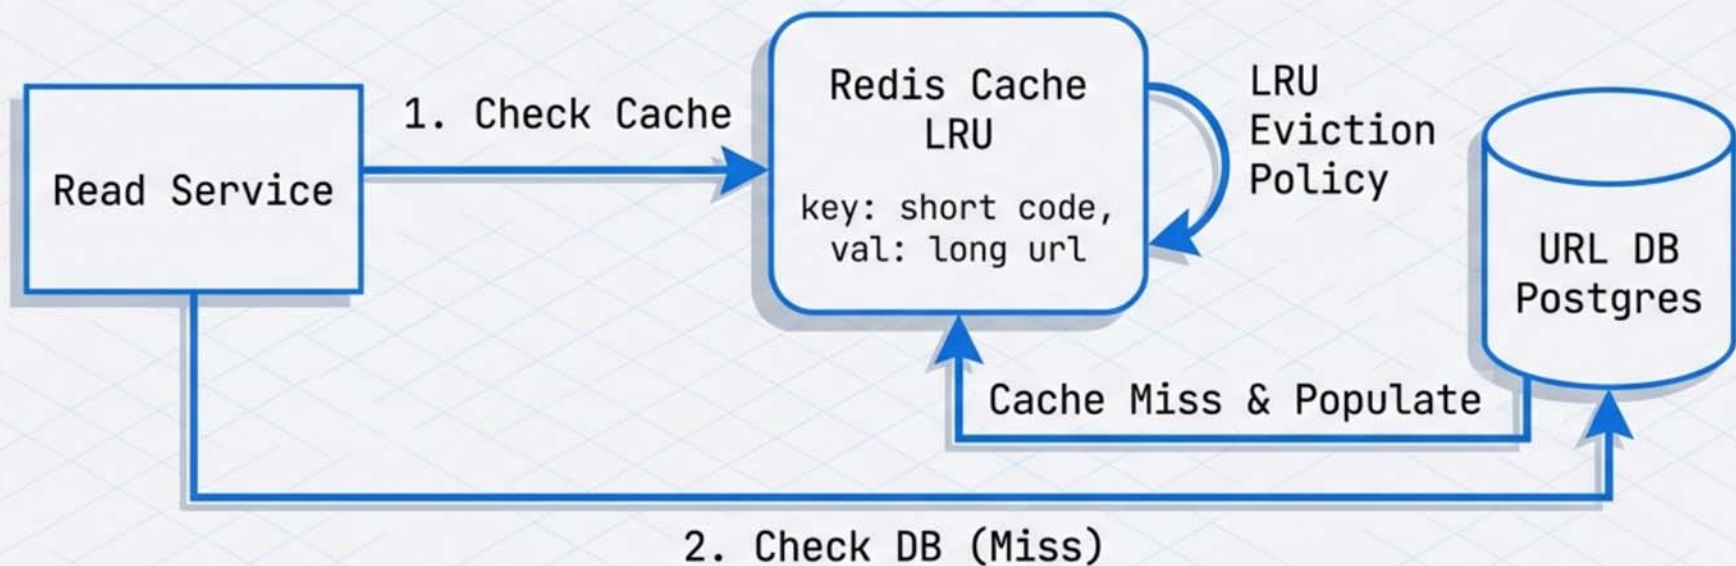

6 characters are enough for 56 Billion URLs.

The Concurrency Problem

Atomic Increment + Range Batching = No Collisions.

Scaling Reads: The Cache Layer

Handles 99% of Read Traffic.

Microservices & Horizontal Scaling

Global Scale: The CDN Layer

Reduces latency to <50ms by serving redirects from the Edge.

The Final Architecture
